

Two new species of the genus *Daphne* from Balkan Peninsula

Dva nové druhy rodu *Daphne* z Balkánu

Josef Halda

HALDA J. (1981): Two new species of the genus *Daphne* from Balkan Peninsula. — Preslia, Praha, 53 : 345 – 347.

Two new species of *Daphne*, *D. skipetarum* (related to *D. jasmina* and *D. malyana*) from Central Albania and *D. velenovskyi* (related *D. striata*) from South Bulgaria are described.

Sedloňov v Orlických horách 1951/3.

Daphne skipetarum HALDA, sp. nova

Fruticulus usque ad 5 cm altus, 10–20 cm in diametro, glaber, trunculo decumbenti vel procumbenti, dichotome ramosissimo, ramis brevissimis, cortice brunneo-griseo vel griseo. Folia alterna, ad apicem ramulorum non conferta, oblongo-ovata, obtusa, non mucronata, basi attenuata, ad marginem revoluta, obscure viridia, coriacea, ± carnosa, nitida, glabra, 5–10 mm longa et 2 mm lata. Flores in racemo terminali 3–8-floro, ebracteato. Perianthium roseum, glabrum; tubus 8–13 mm longus, lobi ± 5 mm lati, triangulares. Bacca nigro-violacea, oblongo-ovata, ± 5 mm longa et 1.5 mm lata.

Typus: Albania centralis: in declivibus lapidosis prope Rogojstnik. Leg. F. PETRAK, IV. 1918, No. 52103, PR.

The collection made by F. Petrak in Albania in 1918 contains one specimen named “*D. petraea* LEYB.”, which, in my opinion, represents a new species. It belongs to sect. *Daphnanthes* subsect. *Oleoides* KAISSL. and is

Fig. 1. — *Daphne skipetarum* HALDA, habit, flower and leaf.

closely related to *D. jasminea* SIBTH. et SM. and *D. malyana* BLEČIČ. It differs by its procumbent stem with short branchlets and leaves oblong-ovate, dark green shiny, obtuse (never mucronate), attenuate at base, strongly revolute in the margin, coriaceous and glabrous. The flowers are narrowly lobed, glabrous, resembling *D. oleoides* SCHREB. The black-violet berries are similar to those of *D. pontica* L. By the shape and colour of fruits this species seems to be quite isolated in the subsection.

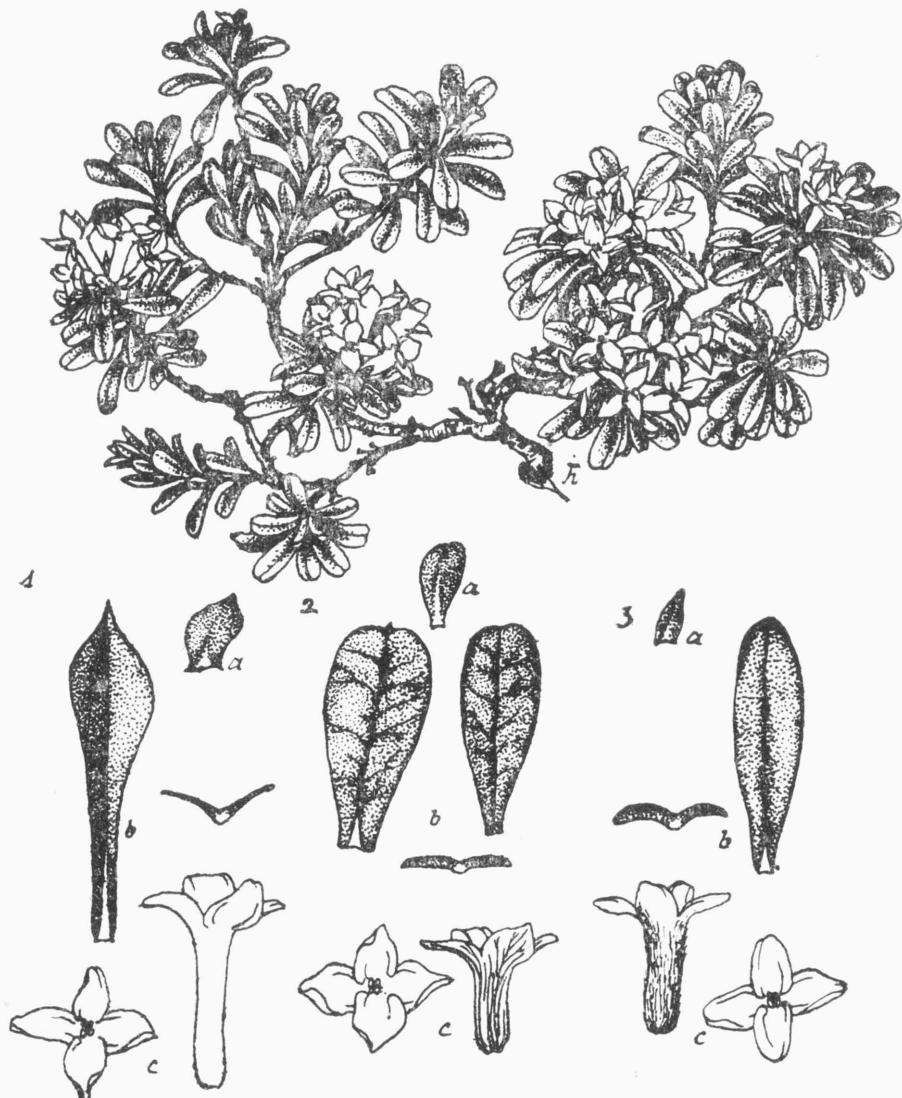

Fig. 2. — 1, *D. striata* TRATT. (a — bract, b — leaf, c — perianth). 2, *D. velenovskyi* HALDA (habit, a — bract, b — leaves, c — perianth). 3, *D. cneorum* L. (a — bract, b — leaf, c — perianth).

Daphne velenovskyi HALDA, sp. nova

Fruticulus glaber, parvus, laxe ramosus, ad 10 cm altus, ca. 15 cm in diametro, breviter procumbens usque adscendens, interdum pulvinatus. Ramuli novelli dilute virides, glaberrimi, vetusti tenues, breves, cinereo-fusci, opaci, manifeste cicatricosi. Folia insigniter glaucescentia, pallida, latitudine 2–3 × longiora, 8–17 mm longa, 5–7(–8) mm lata, obovata usque oblongo-ovata, manifeste retusa vel modice mucronata, matura horizontaliter expansa, tantum ad apicem ramulorum congesta (ramuli inferne nudi), lamina plana, nervo medio incrassato, subtus valde prominente, supra impresso. Capitula terminalis, globosa, 5–14-flora, dense congesta. Bracteae tenues, membranaceae, foliaceae, foliis maturis dimidio minores. Flores odorati. Perianthium roseum; tubus extus purpureo-roseus, semper glaber, numquam pilosus (ut *D. cneorum*), 8–10 mm longus, diametro limbi aequilongus; lobi mucronati, apice involuti. Baccæ lutescens, intida.

A. *D. striata* ramulis tenuibus brevibusque, foliis pallide caeruleo-glaucis, ex apice rotundato mucronatis, tenuioribus, planis, brevioribus et latioribus, bracteis rotundatis vel retusis, tubo perianthii diametro limbi aequilongo differt. A *D. cneorum* ramulis tantum apice foliosis, forma et apice foliorum et tubo perianthii extus semper glabro praesertim distat.

Typus: Bulgaria, montes Pirin: in declivibus graminosis et lapidosis montis Vichren, solo calcareo, 1800–2600 m s.m. Leg. J. HALDA, VII. 1976, PR.

Only *D. cneorum* L., characteristic by its pilose perianth-tube, has been known from Mt. Vichren. The specimens collected by myself in this locality in 1976, have glabrous perianth-tube. I suppose that this poorly known taxon is closely related to *D. striata* TRATT. from the Alps. It differs by its shape of leaves and much shorter perianth-tube, which is as long as the limb diameter (*D. striata* has perianth-tube 2 × longer than the limb). This new species belongs to sect. *Daphnanthes* subsect. *Daphnanthoides* KAISSL. Closely related species include *D. striata* TRATT. and *D. cneorum* L. The latter differs by its pilose perianth-tube 1.5 × longer than the limb diameter and leaves oblong and obtuse.

SOUHRN

Položka lýkovce, sebraná r. 1918 F. Petrakem ve střední Albánii a označená jím jako *D. petraea* LEYB., nalezí novému druhu. Od příbuzných druhů *D. jasmina* SIBTH. et SM. a *D. maliana* BLEČIČ se liší listy podlouhle vejčitými, tupými, k bázi zúženými, podvinutými, kožovitými, lysými. Květy se podobají květům *D. oleoides* SCHREB., černofialovými plody připomíná *D. pontica* L. V subsekci *Oleoides* KAISSL. má druh díky specifickému tvaru a barvě plodů izolované postavení. V r. 1976 nalezl autor tohoto sdělení nový druh lýkovce na Vichrenu v Bulharsku. Dosud byl určován jako *D. cneorum* L., od něhož se liší mj. lysou trubkou květu. Od příbuzného *D. striata* TRATT. se odlišuje kromě tvaru listů o polovinu kratší trubkou květu.
